## How does a superconducting coil store energy?

This system is among the most important technology that can store energy through the flowing a current in a superconducting coil without resistive losses. The energy is then stored in act direct current(DC) electricity form which is a source of a DC magnetic field.

Why do superconducting coils have a ferromagnetic core?

Generally, in the superconducting coils, there exists a ferromagnetic core that promotes the energy storage capacity of SMES due to its ability to store, at low current density, a massive amount of energy. For elevated gain the core configuration is "closed core (CC)". The configuration of (CC) lodges the volume both outside and inside the coil.

How does a superconducting coil withstand a large magnetic field?

Over a medium of huge magnetic fields, the integral can be limited without causing a significant error. When the coil is in its superconducting state, no resistance is observed which allow to create a short circuit at its terminals. Thus, the indefinitely storage of the magnetic energy is possible as no decay of the current takes place.

How to design a superconducting coil system?

When designing an SMES system, the superconducting coil structure must have the best performance depending on the application for which the SMES will be used. The general objective, apart from the minimization of the production cost and the maximization of the discharge speed etc., is to abase the losses over the charges/discharges of the system.

What is the inductance of a multilayer coil?

Multilayer coils were studied by Murgatroyd 9,10 who found that the inductance of the optimal toroid is  $(0.29 L_c)$ . The reduction compared to the Brooks coil is presumably because the toroid generates no stray magnetic field. Murgatroyd reviewed the 5/3 power-law of (2) and other properties of optimal inductors in his excellent summary 9.

How to design a superconducting system?

The first step is to design a system so that the volume density of stored energy is maximum. A configuration for which the magnetic field inside the system is at all points as close as possible to its maximum value is then required. This value will be determined by the currents circulating in the superconducting materials.
