When a low-side switch drives an inductive load, a high voltage is applied to the output terminal because of the back-EMF energy induced when the switch turns off. This back-EMF energy might degrade or damage the IPD. Active clamping is a protective function to absorb the back-EMF energy incurred by the turn-off of the low-side switch.

In a low-voltage DC home, most devices and appliances run on DC voltage, offering increased efficiency due to fewer energy losses compared to AC systems. This simplicity enhances the potential for energy independence, as solar panels, batteries, and efficient appliances can power the home, reducing reliance from the grid.
